

HTML NOTES

DAY 1

1. What is HTML?

→ HTML stands for **HyperText Markup Language**.

→ It is used to **structure content on the web**.

Think of HTML like the **skeleton of a human body**:

- It defines *what exists* on the page
- Headings, paragraphs, images, links—all come from HTML
- Without HTML, a webpage has no structure

Note:

→ HTML is **not a programming language**. It doesn't add logic—it only describes content.

Development setup

VS code - [Download Visual Studio Code - Mac, Linux, Windows](#)

Extensions

- Live-Server: Opens your project in browser instantly
- Live-Preview: Helps you see changes in real time

Boiler Plate Code - concept

→ Every HTML page follows a **basic standard structure**.

It includes:

- Document type declaration
- Root HTML element
- Head section (metadata)
- Body section (visible content)

Think of it like a **template you start every project with**.

2. Basic structure: html, head, body

HTML Tag

- The root of the entire document
- Everything lives inside it

Head Tag

- Contains background information
- Not visible to users
- Includes title, meta info, links to CSS, etc.

Body Tag

- This is what users actually see
- All visible content goes here

3. Headings, paragraph, lists

Headings

- Used to define titles and sections
- Helps in structure and readability

Paragraphs

- Used for writing text content
- Keeps content readable and organized

Lists

→ Two main types:

1. Ordered list (step-by-step)
2. Unordered list (bullet points)

Used in:

- Navigation menus
- Feature lists
- Instructions

4. Div (very important)

→ A **div** is a container.

It helps:

1. Group related elements
2. Structure layout

3. Apply styling later (with CSS)

Think of it like a box that holds content.

Class vs ID

Class

- Can be used multiple times
- Helps style or target a group of elements

ID

- Must be unique
- Used to identify a specific element

Simple way to remember:

- Class = group
- ID = individual
-

5. Links (Anchor Tag)

→ Links are used to **connect pages together**.

They allow users to:

- Navigate between pages
- Open external websites
- Jump within the same page

This is what makes the web a **connected system**, not just static pages.

6. Common Mistakes & Debugging Basics

Common Mistakes

- Forgetting to close tags
- Wrong nesting of elements
- Typing mistakes in tag names
- File not saved properly
- Wrong file extension

Debugging Mindset

When something doesn't work:

1. Check spelling carefully
2. Check opening and closing structure

3. Read error in browser (if visible)
4. Refresh properly
